Determination of tin with arsenic acids. A. I. Portnov
(Odessa State Univ. Inst. Chem. Anal. ~~1954~~)
(1954) — Quadrivalent Sn was pptd. with a 5% soln. of Na (*p*-hydroxyphenyl)arsonate or a 5% soln. of Na (4-hydroxy-3-nitrophenyl)arsonate. With the first of these reagents Sn pptd. even from 0.5% HCl solns. and with the 2nd reagent from 1% HCl solns. With the 1st reagent dissolve the ppt. in 10% NH₄OH and dil. to a definite vol. Place 20-25 ml. of the soln. in a glass-stoppered flask, add HCl to make it 1-2*N*, add 0.5 g. of KBr, and excess of 0.1*N* KBrO₃. After 15 min. add 0.1*N* NaH₂AsO₄ soln. and titrate its excess with KBrO₃ with indigo carmine as indicator. One ml. of 1*N* KBrO₃ = 0.0459 g. Sn (*p*-hydroxyphenyl)arsonate = 0.00918 g. Sn. Another procedure is to dissolve the ppt. in concd. HCl by heating and finish as before. With the 2nd reagent, filter off the ppt. after 1 hr., wash 6-8 times with H₂O or 2-3 times with *N* HCl, place the ppt. in wide-mouthed flask, add 25 ml. 2*N* HCl, and heat on the steam bath to dissolve. Transfer into a 100-ml. volumetric flask and add 2*N* HCl to the mark. Brominate 20-25 ml. of this soln. and finish as before. By this method 0.0198 and 0.0218 g. of Sn was detd. with an error of ±0.0001 g.

247. Determination of penicillin in its compound preparations. S. G. Pugin and A. I. Portnov.

Med
Aptekhas Delo, 1958, 5 (3), 19-22.—The penicillins in procaine penicillin are converted into the relatively stable hydroxamic acids and these are determined colorimetrically in the form of their copper salts. *Procedure*—Dissolve a weighed sample (≈ 0.1 g) of procaine penicillin in about 75 ml of water in a 100-ml calibrated flask. After the flask has been kept at 45° to 50° for 10 to 15 min., cool and make the contents up to 100 ml. Transfer an aliquot of this soln. to a test-tube (19 cm x 2 cm) and dilute the soln. with water to a vol. of 3 to 5 ml. Add 4-5 ml of a mixture of *N* soln. of hydroxyamine hydrochloride and NaOH (pH = 6.0); after 3 to 5 min., add 1 to 1.5 ml of 2 *N* acetic acid soln. and 3 drops of a soln. of CuNO₃ (containing 5% of Cu), and shake the tube. Add 11.5 ml of isobutyl alcohol and mix the contents by gently rotating the tube. Allow the phases to separate for 1 to 2 min., add 0.5 ml of ethanol and carefully mix the contents of the tube by gentle rotation. Measure the colour of the extract in an absorptiometer fitted with a dark-red filter. Carry out a blank experiment to determine the intensity of the colour due to the reagents. For the determination of procaine penicillin, a calibration curve is constructed from results obtained on pure benzylpenicillin.

TITLE: The Use of 2-Sodium- Paraaminobenzoic Acid for the Titrimetric Determination of Cadmium (Primeneniye paraaminobenzoata natriya dlya titrimetricheskogo opredeleniya kadmiya)

PERIODICAL: Zhurnal analiticheskoy khimii, 1958, Vol. 13, Nr 3, pp. 319 - 322 (USSR)

ABSTRACT: Many methods for the quantitative determination of cadmium have been described in publications (Refs 1-7). Complexometric methods for the determination of cadmium have recently grown in importance. When research was undertaken into the influence of substitutes on the solubility of the salts of benzoic acid, it was found that cadmium salts form a hardly soluble compound with 2-sodium-aminobenzoic acid. This observation led to the elaboration of a method for the quantitative determination of the cadmium. This method is based on the precipitation of cadmium by solution of 2-sodium-aminobenzoate and further bromometric determination of the remaining para-aminobenzoic acid in the precipitate. An investigation of the composition of the precipitate resulted in the following formula:

Card 1/3

The Use of 2-Sodium-Paraaminobenzoic Acid for the
Titrimetric Determination of Cadmium

75-13-3-11/27

$(\text{H}_2\text{NC}_6\text{H}_4\text{COO})_2\text{Cd}\cdot 3\text{H}_2\text{O}$. Tests showed that the precipitation of the cadmium begins with a molar relation of Cd: 2-sodium-aminobenzoate - 1 : 1,3 and is complete at a ratio of 1:3,5. A surplus of the reagent has no influence on the accuracy of results obtained. It was further shown, that it is immaterial for the accuracy of the determination how long the precipitate is left to set. The precipitate has well set after 10 to 15 minutes and is easily filterable. Repeated washing with water gives lower results and therefore the precipitate is washed with 70% alcohol, which does not cause any decrease of results even after 10 washings. The precipitation of cadmium according to this method occurs within a pH range of 2 to 6,5 quantitatively. The exactitude of determination is of the same order as that of the gravimetric determination of cadmium according to the sulfate method. With the aid of the method described the following salts of cadmium can be determined: the acetate, the nitrate, the chloride and the iodide of cadmium. Tests have shown that zinc is not precipitated by a solution of 2-sodium-aminobenzoate. Therefore cadmium can be determined

Card 2/3

in the presence of zinc. It was shown, that, even in the presence of a fivefold surplus of zinc satisfactory cadmium determination can be carried out satisfactorily with this new method. There are 8 tables and 10 references, 5 of which are Soviet.

TOPIC TAGS: photoelasticity, resin, plasticizer, refractory coating, composite material

ABSTRACT: The method of preparation and properties of a new optically active material designated as ED6 MTGFA-58 are described. The material was made by mixing (by weight) 58 parts methyltetrahydrophthalic anhydride (MTGFA) into previously molten 100 parts of ED6 epoxy resin at temperature of 65--70C, and adding in sequence one part dibutyl phtalate, and 0.1 part dimethyl aniline. After polymerization the optical constant and modulus of elasticity at hardening and room temperatures were $\sigma_0^{(1.0)} = 0.38 - 0.4 \text{kg/cm} \cdot \text{line}$, $E = 200 - 260 \text{kg/cm}^2$, and $\sigma_1^{(1.0)} = 16.9 - 17 \text{kg/cm}$

Card 1/2

ACC NR: AT7002100

line, $E = (20 - 30) \times 10^3 \text{ kg/cm}^2$, correspondingly. The time-edge effect was small, i.e., 0.5 lines/cm during 20 days storage. The opticomechanical properties were further checked experimentally in actual photoelastic problems whose theoretical solutions were known and it was established that the two practically coincide. Orig. art. has: 4 figures.

TITLE: Comparative Evaluation of Methods for the Calculation of the Characteristics of Transport-type Gas-turbine Engines
(Sravnitel'naya otsenka metodov rascheta kharakteristik transportnogo gazoturbinnogo dvigatelya)

PERIODICAL: Tr. N. -i. labor. dvigateley M-va transp. mashinostr. SSSR, 1957, Nr 3, pp 5-29

ABSTRACT: Formulas for computations are derived, and computations for two-spool transport-type gas-turbine engines are described for three cases: 1) When the characteristics of the compressor and turbines are available; 2) when turbine characteristics are not available, but compressor characteristics are available; and 3) when neither the turbine nor the compressor characteristics are available. For the cases Nrs 2 and 3 it is assumed that the turbine efficiency is a parabolic function of the ratio of the mean peripheral blade velocity to the gas velocity corresponding to adiabatic expansion in the turbine. Therein it is assumed that the flow of gas is independent of the turbine rpm.

Card 1/2

SOV/124-58-4-4020

Comparative Evaluation of Methods (cont.)

Besides, for the third case it is assumed that the adiabatic work of the compressor is a function of the square of the compressor rpm. The following conclusion is made on the basis of the computations performed: For compressor speeds within 80 to 100% design rpm, and for power-turbine speeds within 60 to 80% of design rpm, all three of the methods produce fairly close results. For these conditions the engine power lies between 40 and 100% of the design value.

TITLE: Peculiarities of the Operating Cycle and Selection of the Super-charging Ratio of a High-speed Four-stroke Compression-ignition Engine (Osobennosti rabocheho protsessa i vybor stepeni nadduva bystrokhodnogo chetyrekhtaktnogo dvigatelya s vosplameneniyem ot szhatiya)

PERIODICAL: V sb. : Povysheniye moshchnosti dvigateley s vosplameneniyem ot szhatiya. Moscow, Mashgiz, 1954, pp 81-102

ABSTRACT: A presentation of the results of an experimental investigation of compression-ignition engines with jet-type mixture formation equipped with constant-pressure gas-turbine driven superchargers. The author studies the peculiarities of the operating cycle with moderate supercharging and extreme supercharging of the engine, wherein he designates as "extreme supercharging" that range in which the quantity of heat introduced into the supercharged engine will exceed the amount that can be introduced into the unsupercharged engine. It is shown that an increase in the supercharging

Card 1/2

SOV/124-58-1-507

Peculiarities of the Operating Cycle and Selection of the Supercharging (cont.)

pressure of the air supplied to the engine results in an increase in the work of filling, a decrease in the heat absorbed by the air from the hot walls, and a decrease in the residual-gas coefficient. In either supercharging range these factors vary monotonously. When entering the range of extreme supercharging it is advisable to widen the cross sections of the exhaust organs and to reorganize the exhaust phase in order to minimize the power losses due to the expulsion of the gases. At a given angle of advance of the fuel injection the period of retardation of the fuel ignition will be shortened and the relative amount of fuel injected during that period will be reduced; this will result in a reduction in the cycle-utilization factor and, in turn, in a slack combustion process. The result is a deterioration in fuel economy; hence, such operation is advisable only within a certain intake-air pressure range. The impairment of the indicator economy of the engine with extreme supercharging can be substantially reduced by fitting the fuel-injection characteristics step by step to the unfoldment of the combustion process and by the selection of fuel-injection equipment that would serve to retain the desired duration of the injection period. For extremely highly supercharged engines the development of an engine design suitable for operation at high combustion pressures is especially urgent. An improvement in the turbosupercharger efficiency and an increase in the effectiveness of the air intercooler are also of immediate significance.

TITLE: Heat Recovery Used to Increase Economy of Transport-type Gas-turbine Engines (Regeneratsiya tepla i povysheniye ekonomichnosti transportnogo gazoturbinnogo dvigatelya)

PERIODICAL: Tr. N.-i. labor. dvigateley M-va transp. mashinostr. SSSR, 1957, Nr 3, pp 47-64

ABSTRACT: Three ways of increasing the economy of transport-type gas-turbine engines are examined: 1) improving the gasdynamically effective section, 2) raising the initial temperature and pressure upstream of the turbine, and 3) introducing into the cycle a heat-recovery process. From the calculations of the author it emerges that the most feasible of the three are the last two, of which the author considers the third and last to be the most realistic at present. Studies made of a gas-turbine engine equipped with a heat-recovery unit showed that, from the point of view of the additional bulk and complication involved, the heat-recovery process is expedient only when the relative gain in economy is more than sufficient to compensate

Card 1/2

SOV/124-58-8-8606

Heat Recovery Used to Increase Economy of Transport-type (cont.)

for the extra space required by the heat-recovery unit. Introduction of the heat-recovery process not only lowers the specific fuel consumption under design conditions but affects very favorably the behavior of the specific-fuel-consumption curve throughout the various operating conditions of the engine. The process is particularly effective in the case of engines with a controllable nozzle-junction-box assembly. A comparative study was made of the most promising heat-exchange surfaces, wherein the pressure drop ($\Delta p = 725 \text{ kg/m}^2$) and volumetric flow rates involved [25 liters/(kg/sec)] were held constant in all cases. The following values were obtained for the degree of heat recovery: Surface consisting of smooth-surfaced tubes $\eta = 0.55$; stationary surface consisting of plates $\eta = 0.69$; rotating surface consisting of grids $\eta = 0.76$; rotating surface consisting of plates $\eta = 0.63$. When allowance is made for possible dirt accumulation on the surfaces and for leakage, the degree of heat recovery is roughly as follows: For a stationary heat-recovery unit $\eta = 0.66 - 0.68$; for a rotating heat-recovery unit $\eta = 0.68 - 0.71$. Hence, when it comes to designing a compact, highly efficient heat-recovery unit for gas-turbine engines, consideration should be given not only to the use of rotating heat-exchange surfaces but also to a stationary type comprised of special plates.

L.I. Yezhikina; Tech. Ed.: V.P. Zhukov; Managing Ed. for Literature
on Automotive, Tractor, and Agricultural Machine Building: I.M. Buzasa,
Engineer.

FOURTH: This collection of articles is intended for scientific and engineering
personnel of research institutes and machine-building plants.

COVER: The collection contains reports and papers dealing with better
economy and greater capacities for internal combustion engines. Experimental
results are stated and their effectiveness evaluated. The conference took
place in 1977. The introduction to the collection contains short summaries
of the articles. No personalities are mentioned. References follow
several of the articles.
of loop scavenging are evaluated. The types of diesel engines discussed
are mostly non-Soviet.

50

Forshov, B.A. [Doctor of Technical Sciences, Professor, MVD]. Optima
Compression in a Transport-type Turbopiston Engine
The author analyzes the effects of compression on the basic parameters of
turbopiston-engine performance, the relation of compression to super-
charging, intake-pressure values in supercharging, and effects of
supercharging pressure on various characteristic pressures in the engine.

73

Kraslov, N.A. [Candidate of Technical Sciences, MTU Iseni Buzasa]. Some
Possibilities of Decreasing the Capacity and Efficiency of Two-stroke Tractor
Diesel Engines
The author analyzes the effect of the shape of the exhaust cam and of the
exhaust-valve timing upon the efficiency of an engine with valve-port
scavenging. Other topics discussed in the article include scavenging
efficiency of loop scavenging in a one-cylinder engine, scavenging efficiency
comparison for a Yezh-204 engine, and the amount of supercharging in a
Yezh-204 engine.

89

Vaschenko, V.N. [Candidate of Technical Sciences, TSPDT]. Contributions of
Yezh-204 Toward Improving the Capacities and Efficiencies of Diesel Engines with
Divided Combustion Chambers and Turbulence
The article reviews recent achievements in reducing fuel consumption in
such diesel engines.

105

Sizakov, P.P. [Candidate of Technical Sciences, Docent, MTU Iseni Buzasa].
Maximum Possible Revolutions of a Four-stroke Engine
The author surveys some structural possibilities of increasing the
r.p.m. coefficient and discusses the effects of the size of inlet nozzle
upon the capacity of the engine. Some information is given on gas pen-
etration and methods of computing it.

123

Sizakov, A.K. [Candidate of Technical Sciences, Khar'kovskiy zavod transportnykh
masinobroyeniya Iseni V.A. Malysheva (Khar'kov Transport Machine-building Plant
Iseni V.A. Malyshev)]. Steps Toward the Development of Gas-turbine
Supercharging in Heavy-duty Engines for Diesel Locomotives
The author discusses the problem of supercharging in 2D-100 engines, ana-
lyzes the results of tests of a gas-turbine supercharger on a diesel engine
powered at this plant. After analyzing some of the systems using super-
chargers driven by exhaust-gas turbines, he concludes that the most
efficient and economical method of utilizing exhaust gas is by combining
the kinetic energy of the air (transformed into pressure as it leaves
the turbine wheel) with variable pressure in the outlet. Tests have shown
that fuel consumption in this type of engine is 150 to 155 grams per
effective-horsepower hour.

AUTHOR: Portnov, F., Candidate of Medical Sciences

TITLE: Generators of Aeroions (Generatory aeroionov)

PERIODICAL: Radio, 1958, Nr 10, p 34 (USSR)

ABSTRACT: The author discusses atmospheric ions and their physiological and therapeutic properties, discovered by Soviet scientists (A.P. Sokolov, A.L. Chizhevskiy, L.L. Vasil'yev, A.A. Minkh and others), and the various systems of generating them artificially. One of the first instruments of this kind was the electro-effluvial aeroionizer developed in the USSR by A.L. Chizhevskiy. However, this has many serious shortcomings. In the Laboratoriya aeroionoterapii Instituta eksperimental'noy meditsiny Akademii nauk Latvyskoy SSR (Laboratory of Aeroionotherapy of the Institute of Experimental Medicine of the Academy of Sciences of the Latvian SSR) a portable thermogenerator of aeroions, based on the use of the thermionic emission of incandescent metals, has been developed. In recent times (since 1957), ionizers working on the principle of ball-electric effect, have been used in the laboratory for the generation of aeroions. Such an apparatus has been designed by the author himself in con-

Card 1/2

junction with M. Yeygeles, a Rumanian engineer: a full description is given. When an aerosol ionizer of the above design was tested with P.N. Tverskiy's ionometer, it produced about 200,000 negative and 20,000 positive ions at a distance of 70 cm from the disperser. The ionizer can be used for treating diseases of the upper respiratory passages, high blood pressure and some forms of bronchial asthma; it is being used by the Rumanian Doctors Benedek, G. Ursu and T. Dordea for treating emphysema of the lungs, chronic bronchitis and a few other diseases. There is 1 diagram.

797. CHANGES IN THE CENTRAL SCOTOMA IN PATIENTS WITH HYPERTENSIVE DISEASE TREATED AT THE SEASIDE OF RIGA (Russian text) - Portnov F. G. - TRUD. INST. EKSPER. MED. AKAD. NAUK. LATV. SSR 1956, 12 (37-44)

Investigations were carried out in 63 patients with hypertensive disease (cardiac, cerebral and mixed forms) and also in 9 healthy persons. In the cardiac form roughly in 2/3 of the patients the scotoma remained normal, while in 1/3 it was slightly increased. In the cerebral form the area of the central scotoma was normal only in 3 patients, while in 55 it was enlarged. In the mixed form the size of the scotoma was normal in 5 patients, while enlargement of the area of projection of the blind spot was noted in 43 patients. Improvement in the general state and absence of complaints in patients with hypertensive disease in the course of the health resort treatment is accompanied by decrease of the central scotoma area. Measurement of the scotoma in the stated modifications is a fairly sensitive test, enabling one to determine the severity of a lesion of the visual analyser in patients with hypertensive disease.

Determination of bromine, bromide, and bromate in the presence of one another. H. A. Portnov and S. I. Elkina. *Zhurnal Khim. 13*, 411-13 (1947).--When Br^- , BrO_3^- , and BrO_2^- are present in a neutral soln., it must be remembered that the Br^- and BrO_3^- will react and liberate Br_2 as soon as acid is added. It is best, therefore, first to det. the free Br_2 , which can be done potentiometrically by setting the instrument at 800 mv. and titrating with 0.01 N aniline sulfate soln. standardized against Br_2 water. Then set the instrument at 900 mv., reverse the poles, add an excess of 0.01 N $SbCl_5$ + 2) g. $NaCl$ + 5 ml. of 20% H_2SO_4 , and titrate the excess Sb^{5+} with 0.01 N $KBrO_3$. In both titrations, the galvanometer shows a zero reading at the end point. Finally the Br^- now present in the soln. can be titrated with 0.01 N $NaOCl$ soln. This procedure is a modification of the method of Zintl and Wattenberg (C.A. 17, 702) for the analysis of an aq. soln. contg. Br^- and BrO_3^- . A special Russian titration app. was used which was described by P. and E. in a previous paper (C.A. 40, 2414). The procedure was tested and found fairly satisfactory at Russian plants making Br_2 . TITLE: Change in winding tension during filament winding of glass
reinforced plastic products

15

SOURCE: Mekhanika polimerov, no. 2, 1966, 278-284

TOPIC TAGS: filament winding, filament wound construction, glass
reinforced plastic

ABSTRACT: A filament winding process for prestressed oriented rein-
forced plastics has been investigated. It was shown that the essential
anisotropy of the properties of these materials is the cause of a
change in the initially predetermined winding tension. Based on the
assumption that the materials exhibit linear-elastic behavior, the dis-
tribution of winding tension was investigated for the case of the
winding of a ring onto a rigid mandrel. A calculation method is pro-
posed for determining the change in winding tension and the critical
number of turns above which the pressure on the mandrel remains constant.

13194* (Russian.) Frontal Boundary of a Cavitation Region.
O'perednei granitsy kavitatsionnoi oblasti. L. G. Postnov.
Izvestiya Akademii Nauk SSSR, Otdeleniye Tekhnicheskikh Nauk,
no. 3, Mar. 1957, p. 99-107.

The stability of a stationary temperature field in a moving medium is analyzed for the case when a surface of phase transition is present. A sufficient criterion of instability is established, and when this condition exists, for example, in the case of separated cavitation, the frontal boundary cannot exist in the form of a surface of phase transition, but represents a free surface.

GAS DYNAMICS

AUTHOR: Portnov, I.G. (Moscow).

24-4-14/34

TITLE: On the steady state regimes of the operation of a supersonic gas ejector. (O statsionarnykh rezhimakh raboty sverkhzvukovogo gazovogo ezhektora).

PERIODICAL: "Izv. Ak. Nauk, Otd. Tekh. Nauk" (Bulletin of the Ac. Sc., Technical Sciences Section), 1957, No.4, pp.106-109 (USSR).

ABSTRACT: In the operation of a gas ejector at super-critical flow conditions of the active gas, the presence of a surface of division of the flows at the initial section of the mixing chamber is a characteristic feature. To obtain steady state operation, equilibrium at this surface of sub-division is essential. The conditions of equilibrium of the surface of sub-division determine those steady state conditions which enable steady state operation of a gas ejector with a back pressure inherent in the gasodynamic system, for instance, a system consisting of high pressure and low pressure gas wells, an ejector and a gas collecting tank. It is assumed that outside the cylindrical mixing chamber the movement of the ideal gases is unidimensional and steady, that at the initial section of the mixing chamber the full pressure and the mass of each gas are constant, that there is no heat exchange through the walls and that the c_p/c_v ratio is the same for the active and for the

Card 1/2

On the steady state regimes of the operation of a super-
sonic gas ejector. (Cont.) 24-4-14/34

passive gas and that, owing to the particular selection of the configuration of the Laval nozzle, the influence of the area of intersection of the rarefaction waves is insignificant and that, therefore, cross sections of equal pressures exist in which the movement of the gas can be considered unidimensional. The initial section of the mixing chamber is considered the section which is delimited by the inflow cross section and the cross section of equal pressures. The graphs, p.109, show good agreement of the calculated values with values measured experimentally on ejectors. There are 2 graphs, 3 Russian references.

AUTHOR: PORTNOV, I.G. (Moscow) PA - 3076
TITLE: Concerning the Forward Boundary of the Cavitation Area.
(O peredney granitse kavitatsionnoy oblasti, Russian)
PERIODICAL: Izvestia Akad. Nauk SSSR, 1957, Vol 21, Nr 3, pp 99 - 107
(U.S.S.R.)
Received: 6 / 1957 Reviewed: 7 / 1957

ABSTRACT: An investigation was conducted on the stability of a stationary temperature field in a self-moving medium on whose surface a phase transition is present. The forward boundary was defined as the one between the increasing flow and the area taken by the cavitation. It is taken for granted that an intensive steam generation begins there. The position of the surface of the phase transition ξ is determined not only by the pressure on the position in question of the flow but also by the temperature field in the vicinity of ξ , which is also dependent on the intensity of the steam generation. It is accepted that the physical characteristics are constant and that the magnitude of the temperature cross gradient from one current path to another is small. The equations are derived for heat conductivity in regard to the convective transmission of heat, for the boundary conditions belonging to it, the coupling conditions, and the additional conditions. The solutions of these equations are traced. For a steady case $\xi = 0$ and $\xi = \xi_0$. For this case the equation is deduced out of which ξ_0 can

24-1-8/26

TITLE: The temperature field in the region of cavitation with separations. (Temperaturnoye pole v oblasti sryvnoy kavitatsii).

PERIODICAL: Izvestiya Akademii Nauk, Otdeleniye Tekhnicheskikh Nauk, 1958, No.1, pp. 63-71 (USSR).

ABSTRACT: On the basis of a number of simple assumptions, the amplitude and frequency of temperature oscillations in the region of disruptive cavitation are studied. Cavitation bubbles periodically appear in that region and are limited by a solid wall, a free surface and the surface of phase transition. It is pointed out that cyclic temperature stresses occur which apparently play an important role in bringing about fatigue cavitation disruptions on the surfaces of walls adjoining the cavitation region. By the development of the cavitation bubble is understood a displacement of the surface of phase transition ξ in the moving liquid. The temperature of the phase transition is considered to be constant and equal to u_{ξ} . For this reason the problem is reduced to the determination of the position of the isothermal u_{ξ} as a function of time. It is assumed that temperature changes in the medium are sufficiently small so that the following quantities can be taken to be

Card 1/2

24-1-8/26

The temperature field in the region of cavitation with separations.

constant: density, ρ , thermal capacity at constant pressure, c , thermal conductivity, k . Furthermore, it is assumed that these changes of temperature are such that the effect of energy dissipation on the temperature field is unimportant. The experimental results of Hunsaker (Ref.3) are discussed in terms of the present theory. It is shown that in certain cases cyclic temperature fluctuations of 5 to 10°C may occur which bring about, in the case of steel walls, maximum stresses of 170 to 340 kg/cm². This type of cyclic temperature stress is similar to that observed in boiler tubes under regimes of layered or pulsating steam-water mixtures. The difference between the two is only in the frequency which, in the case of cavitation with separations, is several hundred times as high as in boiler components. The character of the cavitation damage is not determined solely by the cyclic thermal stresses but these play an important and in some cases a decisive role.

Translation from: Referativnyy zhurnal, Mekhanika, 1958, Nr 11, p 70 (USSR)

AUTHOR: Portnov, I. G.

TITLE: The Theory and Design Calculation of the Steady-state Working Regimes of a Supersonic Gas Ejector (Teoriya i raschet statsionarnykh rezhimov raboty sverkhzvukovogo gazovogo ezhektora)

PERIODICAL: Tr. Vses. n.-i. in-t prirodn. gazov, 1958, Nr 2 (10), pp 130-162

ABSTRACT: The paper presents methods of calculation of the steady-state working regimes of a supersonic gas ejector in application to conditions at which the backpressure behind the diffuser is the result of the reciprocal action of all the elements of a gasdynamic system which, besides the ejector, includes gas wells, gas mains, and gas collectors. The basic calculation equations are developed under the normally accepted assumption of a cylindrical form of the mixing chamber, the absence of heat exchange through the walls of the ejector, the complete mixing of the gases after passing the mixing chamber, etc. Another assumption is furthermore made regarding the presence of a certain section in the mixing chamber of the ejector (prior to which the gases do not mix) in which the static pressures of the low-pressure and high-pressure

Card 1/2

SOV/124-58-11-12442

The Theory and Design Calculation of the Steady-state Working Regimes (cont.)

gases are equal and constant over their cross section (a cross section of equal pressures). The author asserts that cross sections of equal pressures do exist, if the profile of the primary gas jet is selected properly. This assertion in a strict sense is inaccurate for a mixing of gases in an ejector with a cylindrical mixing chamber. Originally the hypothesis of the existence of the cross section of equal pressures was advanced in a work of M. D. Millionshchikov and G. M. Ryabinov, no reference to which is made in the paper under review. There are on record several papers which demonstrate that the use of the hypothesis of the existence of a cross section of equal pressures under certain specified conditions produces a fundamental discrepancy in calculated values as compared to experimental ones. Several examples of the design of ejectors by the author's methods are presented. Considerations are set forth for the calculation of the influence of friction against the sides of the mixing chamber on the operational characteristics of the gas ejector. A comparison is made of calculated and experimental results. Bibliography: 7 references.

REPROD: This collection of articles is intended for scientists, engineers, and technicians associated with the gas industry.

COVERAGE: The articles discuss the development of gas fields, natural gas recovery, gas transportation, and subsurface gas conservation. The field operating conditions are analyzed from the commercial point of view. The author notes that due to specific geological conditions prevailing in the USSR during the application of gas extraction methods of the type used in the United States, it is not always advisable to copy the methods of the United States development of gas fields. Individual articles discuss problems of the inflow, the study of gas well narrow oil containing fringes, the theory of gas study of gas condensates. A number of articles are devoted to the study of stabilized gas flow in pipelines, and discuss theoretical problems connected with the performance of gas ejectors and separators. The authors also deal with corrosion of the inner surface of gas pipelines. The authors also deal with the authors are supported by mathematical calculations. No personalities are mentioned. References accompany each article.

Yessouary nauchno-issledovatel'skiy Institut prirodnikh gazov

Razrabotka i ekspluatatsiya gazovykh mestozhiznitsy, transportnaya (Development and Exploitation of Gas Fields, Transportation of Gas) Moscow, Gosizdatkhim, 1959, 353 p. (Series: IZS: Trudy, 5/13) Errata slip inserted. 1,500 copies printed.

Sponsoring Agency: Otdelnoye upravleniye gazovoy promyshlennosti pri Sovetskom Ministre BHKh.

Ed.: Ye. M. Minshly and V.L. Babanin; Exec. Ed.: M.P. Maryonov; Tech. Ed.: A.S. Polunina.

PURPOSE: This collection of articles is intended for scientists, engineers, and technicians associated with the gas industry.

CONTENTS: The articles discuss the development of gas fields, natural gas recovery, gas transportation, and subsurface gas conservation. One field operating conditions are analyzed from the commercial point of view. The author notes that due to the specific geological conditions prevailing in the USSR, the application of gas extraction methods of the type common in the USA is not always advantageous. Individual articles discuss: (1) the theory of development of gas fields with narrow oil columns; (2) filtration dynamics, and the inflow, the study of gas well periods of gas well filtration dynamics, and the study of gas condensate; (3) a number of articles are devoted to the study of un-stabilized gas flow in pipelines and discuss theoretical problems connected with the performance of the inner surface of gas pipelines. The authors also deal with the construction of the inner surface of gas pipelines. Conclusions made by the authors are supported by mathematical calculations. So personalities are mentioned. References accompany each article.

AUTHOR: Portnov, I.G.

TITLE: Consideration of Condensation and Heat Conduction of the Steam
for the Investigation of the Collapse of a Spherical Bubble

PERIODICAL: Vestnik Moskovskogo universiteta. Seriya I. Matematika,
mekhanika, 1960, No. 6, pp. 84 - 93

TEXT: In an infinite, incompressible fluid without weight the author considers a bubble filled with steam with the initial radius ξ_0 . Let the steam be condensed almost dry; let the temperature and the pressure in the bubble be functions of the time only. For a diminution of the bubble, the steam condenses at the walls, the nascent heat is supplied to the steam and the fluid. The author establishes the equations and boundary conditions of the processes taking place for three regions: spherical region of the pure steam, a spherical shell consisting of condenser water, remaining region of the fluid. Then the very complicated system of equations is simplified under the assumption that $\xi_0 \ll 1$, $\rho_1/\rho_2 \ll 1$, where ρ_1 is the density of the steam and ρ_2 is the density of the water. For the Card 1/4

B104/B102

Exact solution of the ...

$u_i(x, t)$ is the temperature; k_i and a_i are the thermal conductivity and diffusivity; λ is the latent phase transition heat; ρ is the density; the subscripts 1 and 2 refer to solid and liquid phase; x_0 and t_0 are the scale units of length and time. $\xi(\tau) \frac{\partial v}{\partial \tau} + \xi(\tau) \xi'(\tau) p \frac{\partial v}{\partial p} = p^2 v$ (6) is obtained

by substituting $t = \tau$ and $x = y(\tau)$ at $u_2 \equiv 0$ with the aid of a Laplace transformation. The temperature field is determined by a Poisson integral, and an exact solution of the problem is obtained. Proceeding from an approximate formula, and exact solution is obtained also for the velocity of the phase transition interface. There are 3 Soviet references.

TITLE: Fusion of a two layer plate

SOURCE: Teplo- i massoperenos. t. III: Teplo- i massoperenos pri fazovykh prevrashcheniyakh (Heat and mass transfer. v. 3: Heat and mass transfer in phase transformations). Minsk, Nauka i tekhnika, 1965, 286-298

TOPIC TAGS: heat of fusion, heat conductivity, conductive heat transfer

ABSTRACT: Assuming that the coefficients of heat conductivity k_1 and thermal diffusivity a_1 , the latent heat of phase transition λ , and the density ρ_i ($i = 1, 2$) are constant, we write the system of equations and the supplementary conditions for the one dimensional problem of the fusion of a two layer plate. The heat conductivity equation for the first plate is

$$\frac{\partial u_1}{\partial t} = a_1 \frac{\partial^2 u_1}{\partial x^2} \quad (\xi < x < l), \quad (1)$$

Card 1/3

L 40877-66

ACC NR: AT6021845

The heat conductivity equation for the second plate is

$$\frac{\partial u_2}{\partial t} = a_2 \frac{\partial^2 u_2}{\partial x^2} \quad (l < x < b), \quad (2)$$

The conditions for the phase transition surface are

$$(u_1)_\xi = 0, \quad Q(t) + k_1 \left(\frac{\partial u_1}{\partial x} \right)_\xi = \lambda \rho \frac{d\xi}{dt}, \quad (3)$$

The conditions for the contact surface of the plates are

$$u_1 = u_2, \quad k_1 \frac{\partial u_1}{\partial x} = k_2 \frac{\partial u_2}{\partial x} \quad \text{при } x = l, \quad (4)$$

The condition for the free surface of the second plate is

$$u_2 = -u_0 \quad \text{при } x = b, \quad (5)$$

The initial conditions are

$$\xi = 0, \quad u_1 = -u_0, \quad u_2 = -u_0 \quad \text{при } t = 0. \quad (6)$$

Here x and t are a coordinate and the time; u_1 is the temperature, calculated from the temperature of the phase transition; $Q(t)$ is the heat flux; $l - \xi$ is the thickness of the first plate; $b - l$ is the

Card 2/3

L 40877-65

ACC NR: AT6021845

thickness of the second plate; ξ (t) is the coordinate of the moving phase boundary; subscripts 1 and 2 refer respectively to the first and second plates. The author solves the problem by the introduction of dimensionless variables. Sample numerical calculations are given. Orig. art. has: 64 formulas.

TITLE:

A Universal Device for Measuring the Torsion Angle When
Determining the Shear Modulus on a Torsion-testing Machine

PERIODICAL:

Zavodskaya laboratoriya, 1959, Vol 25, Nr 10, pp 1245 - 1246
(USSR)

ABSTRACT:

A device was developed, which makes it possible to measure the angle of twist on differently dimensioned samples (diameter 5 to 20 mm, length 100 to 250 mm) irrespective of the construction of the test machine. The measuring accuracy of the device is 0.0001 radian. By fastening the device immediately on to the sample the measuring error which occurs with other measuring methods is avoided. The device (Figure) is fastened to the sample by means of a bracket and two slitted plugs, one of which is fitted with a measuring scale graduated from 0 to 110 mm, as well as with an indicator which shows the angle of twist (after multiplication of the value read off from the scale with the conversion coefficient of the device $A = 0.0001$). From the value of the angle of twist (expressed in radian) and the corresponding moment of torsion (in kg.cm) the modulus of shear in torsion may be calculated according to the well-known equation.
